A Bayesian Approach to Jointly Estimate Tire Radii and Vehicle Trajectory

Emre Özkan, Christian Lundquist and Fredrik Gustafsson

Abstract—High-precision estimation of vehicle tire radii is considered, based on measurements on individual wheel speeds and absolute position from a global navigation satellite system (GNSS). The wheel speed measurements are subject to noise with time-varying covariance that depends mainly on the road surface. The novelty lies in a Bayesian approach to estimate online the time-varying radii and noise parameters using a marginalized particle filter, where no model approximations are needed such as in previously proposed algorithms based on the extended Kalman filter. Field tests show that the absolute radius can be estimated with millimeter accuracy, while the relative wheel radius on one axle is estimated with submillimeter accuracy.

I. INTRODUCTION

Tire pressure monitoring has become an integral part of todays’ automotive active safety concept. With the announcement of US standard (FMVSS 138) and European standard (ECE R-64) vehicle manufacturer must provide a robust solution to early detect tire pressure loss. A direct way to measure the tire pressure is by equipping the wheel with a pressure sensor and transmitting the information wireless to the body. This is costly and therefore indirect solutions have been introduced on the market lately, see e.g., [1]. In this paper an indirect approach is presented where the tire radius is estimated simultaneously with the vehicle trajectory. This is done under the assumption that there is a relation between a reduction in tire radius and tire pressure.

The indirect approach presented in [1] is only based on the wheel speed sensors and it is shown how a tire pressure loss in one wheel leads to a relative radii error between the wheels. In later publications GPS measurements has also been included to improve the radius estimation and even make it possible to estimate the absolute radius of one tire. The effective tire radius is estimated using a simple least-squares regression technique in [2]. A second order sliding mode observer is used to estimate the tire radius errors given the measurements. The unknown wheel radii effect the state through the wheel speed sensor. The angular velocities of the wheels and GPS positions are used as the inputs and the measurements, respectively. Our aim is to jointly estimate the state trajectory and the unknown tire radii effect the state through the wheel speed sensor. The state vector is defined as the planar position and the heading angle of the vehicle,

\[ \mathbf{x} = \begin{bmatrix} x & y & \psi \end{bmatrix}^T. \]  

The discrete time model for the evolution of the state is given as,

\[ x_{k+1} = x_k + T v_x \cos \psi_k \] (2a)
\[ y_{k+1} = y_k + T v_y \sin \psi_k \] (2b)
\[ \psi_{k+1} = \psi_k + T \dot{\psi}_k. \] (2c)

The available raw signals are the angular velocities of the wheels which can be measured by the ABS sensors. The angular velocities can be converted to virtual measurements of the absolute longitudinal velocity and yaw rate as described in [9], [10], assuming a front wheel driven vehicle with slip.

The measurements defined as above have bias terms which are unknown and need to be estimated on the run. The wheel radius errors are defined as the difference between the actual and the nominal values of the rear left and right wheel radii \( \delta_3 \triangleq r_3 - r \) and \( \delta_4 \triangleq r_4 - r \), respectively. Here, the nominal value of the wheel radius is denoted \( r \) and equivalently

\[
\begin{align*}
r_3 &= r + \delta_3 \quad (4a) \\
r_4 &= r + \delta_4. \quad (4b)
\end{align*}
\]

Substituting (4) in equations (3) results in

\[
\begin{align*}
v^\text{virt} &= \frac{\omega_3 r_3 + \omega_4 r_4}{2} = v + \frac{\omega_3 \delta_3}{2} + \frac{\omega_4 \delta_4}{2} \quad (5a) \\
\dot{\psi}^\text{virt} &= \frac{\omega_4 r_4 - \omega_3 r_3}{B} = \dot{\psi} + \frac{\omega_4 \delta_4}{B} - \frac{\omega_3 \delta_3}{B}. \quad (5b)
\end{align*}
\]

The measurements defined as above have bias terms which are functions of \( \delta_3 \) and \( \delta_4 \). By using the virtual measurements as the inputs, the motion model (2) can be rewritten according to

\[
\begin{align*}
x_{k+1} &= x_k + T(v^\text{virt}) = x_k + \frac{\omega_3 \delta_3}{2} - \frac{\omega_4 \delta_4}{2} \cos \psi_k \quad (6a) \\
y_{k+1} &= y_k + T(\dot{v}^\text{virt}) = y_k + \frac{\omega_3 \delta_3}{2} - \frac{\omega_4 \delta_4}{2} \sin \psi_k \quad (6b) \\
\psi_{k+1} &= \psi_k + T(\dot{\psi}^\text{virt}) = \psi_k + \frac{\omega_4 \delta_4}{B} + \frac{\omega_3 \delta_3}{B}. \quad (6c)
\end{align*}
\]

The equations given above can be rewritten in the form of

\[
\begin{align*}
x_k &= f(x_{k-1}, u_k) + g(x_{k-1}, u_k)w_k, \quad (7a) \\
y_k &= h(x_k, u_k) + e_k. \quad (7b)
\end{align*}
\]

where where \( u_k \) is the virtual measurements used as the inputs and the noise term \( w_k \) is assumed to be Gaussian,

\[
w_k = \mathcal{N}\left(\begin{pmatrix} \delta_3 \\ \delta_4 \end{pmatrix}, \begin{pmatrix} \Sigma_3 & 0 \\ 0 & \Sigma_4 \end{pmatrix}\right). \quad (8)
\]

The parameters aimed at estimating are the radii error bias and the covariances,

\[
\theta = \{\delta_3, \delta_4, \Sigma_3, \Sigma_4\}. \quad (9)
\]

The sensor model (7b) is describing the relation with the GPS position and the state variables according to

\[
\begin{bmatrix} x_{k,\text{GPS}} \\ y_{k,\text{GPS}} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix} x_k + e_k. \quad (10)
\]

where \( e_k \) is the measurement noise. In the following section we describe the estimation of the unknown bias terms and the covariances jointly with the state in a Bayesian framework.

### III. Parameter and State Estimation

In the Bayesian approach, we will utilize suitable prior distributions for the unknowns and compute the posterior joint density recursively. The inference will be done by using marginalized particle filters [11] where the unknown noise parameters are marginalized out in relevant steps. Our approach described here heavily relies on marginalization and conjugate priors concepts. Before introducing the details of the particle algorithm here we shortly repeat some preliminary information.

#### A. Posterior Distribution for the Conjugate Prior

For multivariate Normal data \( z \) with unknown mean \( \mu \) and covariance \( \Sigma \), a Normal-inverse-Wishart distribution defines a conjugate prior\(^1\). Let us denote it as \( [\mu, \Sigma] \sim \text{NIW}(\nu, V) \). The Normal-inverse-Wishart distribution defines a hierarchical Bayesian model given below:

\[
\begin{align*}
z | \mu, \Sigma &\sim \mathcal{N}(\mu, \Sigma) \quad (11) \\
\mu | \Sigma &\sim \mathcal{N}(\hat{\mu}, \hat{\Sigma}) \quad (12) \\
\Sigma &\sim \text{IW}(\nu - d, \Lambda) \quad (13)
\end{align*}
\]

where \( \text{IW}(\cdot) \) denotes the Inverse Wishart distribution and \( d \) denotes the dimension of measurement vector \( z \). The parameters \( \nu \) and \( V \) represent the sufficient statistics and can be updated recursively with the new data. The relevant quantities are defined as,

\[
\begin{align*}
\hat{\mu} &\triangleq V_{11}^{-1} V_{1z}, \quad (14) \\
\hat{\Sigma} &\triangleq V_{11}^{-1} \Sigma, \quad (15) \\
\Lambda &\triangleq V_{zz} - V_{1z} V_{11}^{-1} V_{z1}, \quad (16) \\
V &\triangleq \begin{bmatrix} V_{zz} & V_{1z} \\ V_{z1} & V_{11} \end{bmatrix}, \quad (17)
\end{align*}
\]

where \( V_{zz} \) is defined as the upper-left \( d \times d \) sub-block of \( V \in \mathbb{R}^{(d+1) \times (d+1)} \).

\(^1\) A family of prior distributions is conjugate to a particular likelihood function if the posterior distribution belongs to the same family as the prior.
The joint density of $(\mu, \Sigma)$ is of the form

$$p(\mu, \Sigma) = N_{\text{IW}}(\nu, V)$$

$$= \frac{1}{c} |\Sigma|^{-\frac{\nu + d + 1}{2}}$$

$$\times \exp \left( -\frac{1}{2} \text{tr}(\Sigma^{-1}[I_d, \mu]V[-I_d, \mu]^T) \right),$$

(19)

where $c$ is the normalizing constant.

Via conjugacy, the posterior distribution is again a normal-inverse-Wishart distribution with updated statistics. The update equations of the statistics are as follows,

$$V_k = \lambda V_{k-1} + \left[ \frac{z_k}{1} \right] \left[ \frac{z_k^T}{1} \right],$$

$$\nu_k = \nu_{k-1} + 1.$$  

where the scalar real number $0 \leq \lambda \leq 1$ is defined as the forgetting factor. The use of the forgetting factor corresponds to the application of an exponential window on the collected statistics with effective length $h = \frac{1}{1-\lambda}$. The statistics relies on roughly the measurements within the last $h$ frames/time instances. That allows the algorithm to adapt the changes in the noise statistics in time.

The recursive equations enable us to propagate the sufficient statistics easily in time. Furthermore, the predictive distribution for $z$ becomes a $t$-distribution for a NiW prior.

$$p(z_k|z_{1:k-1}, \nu_0, V_0) = p(z_k|\nu_{k-1}, V_{k-1}) = St_{\nu-d+1}(\mu, \Lambda)$$

(21a)

where

$$\mu = V_{11}^{-1}V_{1z}$$

$$\Lambda = \frac{(1 + V_{11})}{(\nu - d + 1)}(V_{zz} - V_{1z}V_{11}^{-1}V_{z1})$$

(21b)

$St_{\nu}(\mu, \nu)$ is the multivariate student-$t$ distribution with $\nu$ degrees of freedom, located at $\mu$ with scale parameter $\Lambda$.

B. Marginalization in nonlinear filtering

Let us define NiW priors for the unknown process noise sequences of the system defined by (7a) and (7b). Our aim is to approximate the joint density $p(x_{0:k}, \theta|y_{0:k})$ and allow marginalization if possible. The joint distribution of the states and the unknown parameters can be decomposed into the conditional distributions as follows.

$$p(x_{0:k}, \theta|y_{0:k}) = p(\theta|x_{0:k}, y_{0:k})p(x_{0:k}|y_{0:k}).$$

(22)

Suppose we approximate the distribution $p(x_{0:k}|y_{0:k})$ by a set of $N$ particles and their weights as

$$p(x_{0:k}|y_{0:k}) \approx \frac{1}{N} \sum_{i=1}^{N} \omega_k^{(i)} \delta_{x_{0:k}^{(i)}}(.)$$

(23)

For each particle we can compute analytical expressions for the posterior distribution of the unknown parameters of the process noise. The posterior follows the normal-inverse-Wishart distribution and the sufficient statistics are updated at each time step, for each particle, according to Equations (20a)-(20b) where we define the pseudo measurements $z_k$ as follows,

$$z_k \triangleq g^\dagger(x_{k-1}, u_k)(x_k - f(x_{k-1}, u_k))$$

(24)

where $g^\dagger(x_{k-1}, u_k)$ is the pseudo-inverse of the matrix $g_k(x_{k-1}, u_k)$ in (7a). For a given state trajectory $x_{0:k}$ and the measurements $y_{0:k}$ the pseudo measurements can be computed directly. Using the sequential importance sampling scheme for propagating the particle approximation (23) leads to the standard weight update equation:

$$\omega_k^{(i)} = \omega_k^{(i)} \frac{p(y_k|x_k^{(i)})p(x_k^{(i)}|x_{0:k-1}^{(i)}, y_{0:k-1})}{q(x_k^{(i)}|x_{0:k-1}^{(i)}, y_{0:k-1})},$$

(25)

where $q(.)$ is the importance distribution from which we sample $x_k^{(i)}$.

C. State prediction

In computing the state transition density $p(x_k|x_{0:k-1}, y_{0:k-1})$, one can utilize the posterior distribution of the unknown parameters that are computed for each particle. One important advantage of using conjugate priors reveals itself here as it is possible to integrate out unknown noise parameters as they follow normal-inverse-Wishart distribution.

$$p(x_k|x_{0:k-1}, y_{0:k-1}) = \int p(x_k|x_{0:k-1}, \theta)p(\theta|x_{0:k-1}, y_{0:k-1})d\theta.$$  

(26)

For each particle $i$, the distribution can be written as:

$$p(x_k|x_{0:k-1}^{(i)}, y_{0:k-1}) = p_{x_k}(g^\dagger(x_{k-1}, u_k)(x_k - f(x_{k-1}^{(i)}, u_k))|x_{0:k-1}^{(i)}, y_{0:k-1})$$

(27)

$$= p_{x_k}(g^\dagger(x_{k-1}, u_k)(x_k - f(x_{k-1}^{(i)}, u_k))|x_{1:k-1}^{(i)}, y_{1:k-1}^{(i)})$$

(28)

$$= p_{x_k}(g^\dagger(x_{k-1}, u_k)(x_k - f(x_{k-1}^{(i)}, u_k))|x_{1:k-1}^{(i)}, V_{1:k-1}^{(i)})$$

(29)

The resulting predictive distribution is a multivariate Student-$t$ distribution given in (21).

At the sampling stage, in most of the cases it is not possible to sample from the optimal importance distribution. The state transition density $p(x_k|x_{0:k-1}, y_{0:k-1})$ can be used as the importance distribution. In that case the weight update equation (25) reduces to,

$$\omega_k^{(i)} = \omega_k^{(i)} \frac{p(y_k|x_k^{(i)})}{q(x_k^{(i)}|x_{0:k-1}^{(i)}, y_{0:k-1})}.$$  

(30)

Moreover computation of the pseudo inverse $g^\dagger(x_{k-1}, u_k)$ becomes no longer necessary. That is because when $g^\dagger(x_k^{(i)}|x_{0:k-1}^{(i)}, y_{0:k})$ is chosen as $p(x_k|x_{0:k-1}^{(i)}, y_{0:k-1})$, one first samples from (21) in order to sample $x_k^{(i)}$. Then the samples from (21) can be used directly in the statistics update (20a)-(20b). The pseudo code of the simplified algorithm used in the simulations is given in Table I.

In the proposed method, each particle keeps its own estimate for the parameters of the unknown process noise.
and the measurement noise. In the importance sampling step, the particles use their own posterior distribution of the unknown parameters. The weight update of the particles is made according to the measurement likelihood. The particles, keeping the unknown parameters which best explains fits to the observed measurement sequence will survive in time.

D. Posterior Distribution for the Noise Parameters

The marginal posterior density of the unknown parameters can be computed by integrating out the states in the joint density.

\[
 p(\theta | y_{1:k}) = \int p(\theta | x_{0:k}, y_{1:k})p(x_{0:k} | y_{1:k})dx_{0:k}
\]

\[
 \approx \sum_{i=1}^{N} \omega_k^{(i)} p(\theta | x_{0:k}^{(i)}, y_{1:k}^{(i)}). \tag{31}
\]

Then the estimate of the unknown parameters could be computed according to a chosen criterion. As an example, according to the minimum mean square error (MMSE) criterion, the noise variance estimate at time \( t \) could be computed as

\[
 \tilde{\omega}_k^{(i)} = \frac{\omega_k^{(i)} \Lambda_k^{(i)}}{v_k - 1}, \tag{32}
\]

where the weights are inherited from the particles.

IV. RESULTS

Measurements were collected with a passenger car equipped with standard vehicle sensors, such as wheel speed sensors, and a GPS receiver, see Figure 2. The vehicle is further equipped with an additional and more accurate IMU, besides the standard IMU already mounted in the car, and an optical velocity sensor. These two additional sensors were used to calibrate the setup, but were not further used to produce the results presented.

In regions where the car moves at low velocities, we utilize the steering wheel angle measurement as follows, in order to avoid quantization problems of the wheel Cox

\[
 x_{k+1} = x_k + T(\psi_{k}^{\text{virt}} - \omega_3 \delta_3 - \omega_4 \delta_4) \cos \psi_k \tag{33a}
\]

\[
 y_{k+1} = y_k + T(\psi_{k}^{\text{virt}} - \omega_3 \delta_3 - \omega_4 \delta_4) \sin \psi_k \tag{33b}
\]

\[
 \psi_{k+1} = \begin{cases} 
 \psi_k + T\left(\psi_{k}^{\text{virt}} - \frac{\omega_3 \delta_3}{l} + \frac{\omega_4 \delta_4}{l}\right) & \text{if } \nu > \gamma \\
 \psi_k + T\delta_F(\psi_{k}^{\text{virt}} - \frac{\omega_3 \delta_3}{2} - \frac{\omega_4 \delta_4}{2}) / l_b & \text{if } \nu < \gamma 
\end{cases} \tag{33c}
\]

The GPS measurements of the 12 km test round is shown as a black solid line in Figure 3. The round took about 18 min to drive and it starts and ends in urban area of Linköping, in the upper right corner in Figure 3. The test vehicle is driving clockwise, first on a small rural road, and then on the left side of the figure entering a straight national highway, before driving back to urban area on the top of the figure. The gray dashed line shows the estimated trajectory of the vehicle.

Fig. 2. The test vehicle of Linköping University is logging standard CAN data. The vehicle is in addition equipped with a GPS receiver, an IMU and an optical velocity sensor.
The black line is GPS position measurements and the gray line is the estimated driven trajectory. The experiment starts and ends at a roundabout in the upper right corner.

Fig. 4. Tire radius error of the left rear wheel. The upper plot shows the mean value $\delta_3$ and the lower plot the covariance estimate $\Sigma_3$. The black solid line is the estimated values from the first experiment, with balanced wheel pressure, and the gray line shows the estimate from the second experiment where the pressure of the left wheel is reduced by 50%. The tire pressure loss lead to a radius reduction of about 1.5 mm.

Fig. 5. Tire radius error of the right rear wheel. The upper plot shows the mean value $\delta_4$ and the lower plot the covariance estimate $\Sigma_4$. The black solid line is the estimated values from the first experiment, with balanced wheel pressure, and the gray line shows the estimate from the second experiment where the pressure of the right wheel is unchanged.

Fig. 6. Tire radius error difference between the left and the right rear wheels. The black solid line is the estimated values from the first experiment, with balanced wheel pressure, and the gray line shows the estimate from the second experiment where the pressure of the left wheel is reduced by 50%. The tire pressure loss lead to a radius reduction of about 1.5 mm.

V. Conclusion

In this study, we address the problem of joint estimation of unknown tire radii and the trajectory of a four wheeled vehicle based on GPS and wheel angular velocity measurements. The problem is defined in Bayesian framework and an efficient method that utilizes marginalized particle filters is proposed in order to accomplish the difficult task of joint parameter and state estimation. The algorithm is tested on real data experiments. The results show that it is possible to estimate relative tire radius difference within sub-millimeter accuracy.
